

A Somewhat Informal Introduction to FHE

David Wu

August, 2014

Basic Definitions

Homomorphic Encryption

Homomorphic encryption scheme: encryption scheme that allows computation on ciphertexts

Comprises of three functions:

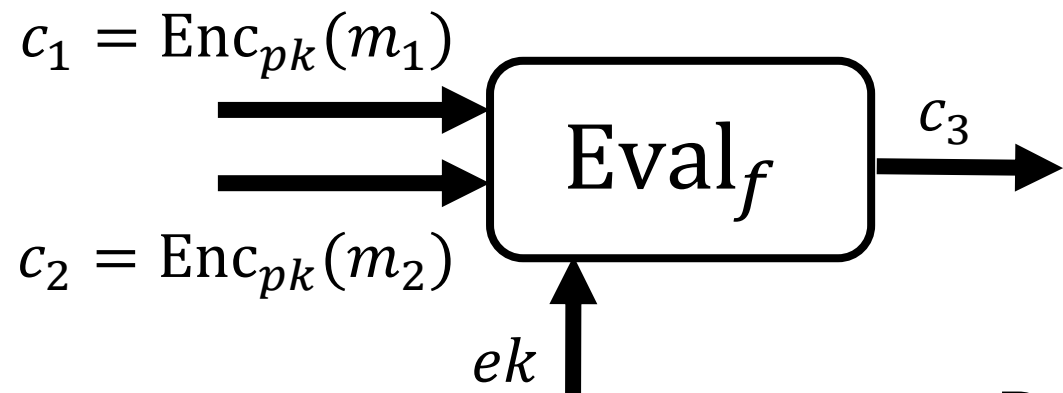

Must satisfy usual notion of semantic security

Homomorphic Encryption

Homomorphic encryption scheme: encryption scheme that allows computation on ciphertexts

Comprises of three functions:

$$\text{Dec}_{sk} \left(\text{Eval}_f(ek, c_1, c_2) \right) = f(m_1, m_2)$$

Fully Homomorphic Encryption (FHE)

Many homomorphic encryption schemes:

- ElGamal: $f(m_0, m_1) = m_0 m_1$
- Paillier: $f(m_0, m_1) = m_0 + m_1$
- Goldwasser-Micali: $f(m_0, m_1) = m_0 \oplus m_1$

Fully homomorphic encryption: homomorphic with respect to **two** operations: addition and multiplication

- Can evaluate Boolean and arithmetic circuits
- [BGN05]: one multiplication, many additions
- [Gen09]: first FHE construction from lattices

Fully Homomorphic Encryption

Correctness: $\text{Dec}_{sk} \left(\text{Eval}_f(ek, c_1, c_2) \right) = f(m_1, m_2)$

Circuit Privacy: $\text{Enc}_{pk}(\mathcal{C}(m_1, m_2)) \approx \text{Eval}_f(ek, c_1, c_2)$

Compactness: Decryption circuit has size at most $\text{poly}(\lambda)$

Lattices and LWE

Lattices

All known FHE constructions based on lattice problems

Lattices are discrete additive subgroups

basis vectors

equivalent definition: the set of **integer**
combination of basis vectors

discrete subgroup: no other lattice point contained
in ball of radius $\epsilon > 0$ around each lattice point

Hard Lattice Problems

Finding a short vector in a lattice (SVP)

“Good” basis: easy

“Bad” basis: not so easy

Exact SVP is NP-hard. Approximation algorithms try to find a

“good” basis using lattice-reduction techniques

Learning with Errors (LWE) [Reg05]

$$A \stackrel{\$}{\leftarrow} \mathbb{Z}_q^{m \times n}$$

$$b \stackrel{\$}{\leftarrow} \mathbb{Z}_q^m$$

$$A \stackrel{\$}{\leftarrow} \mathbb{Z}_q^{m \times n}$$

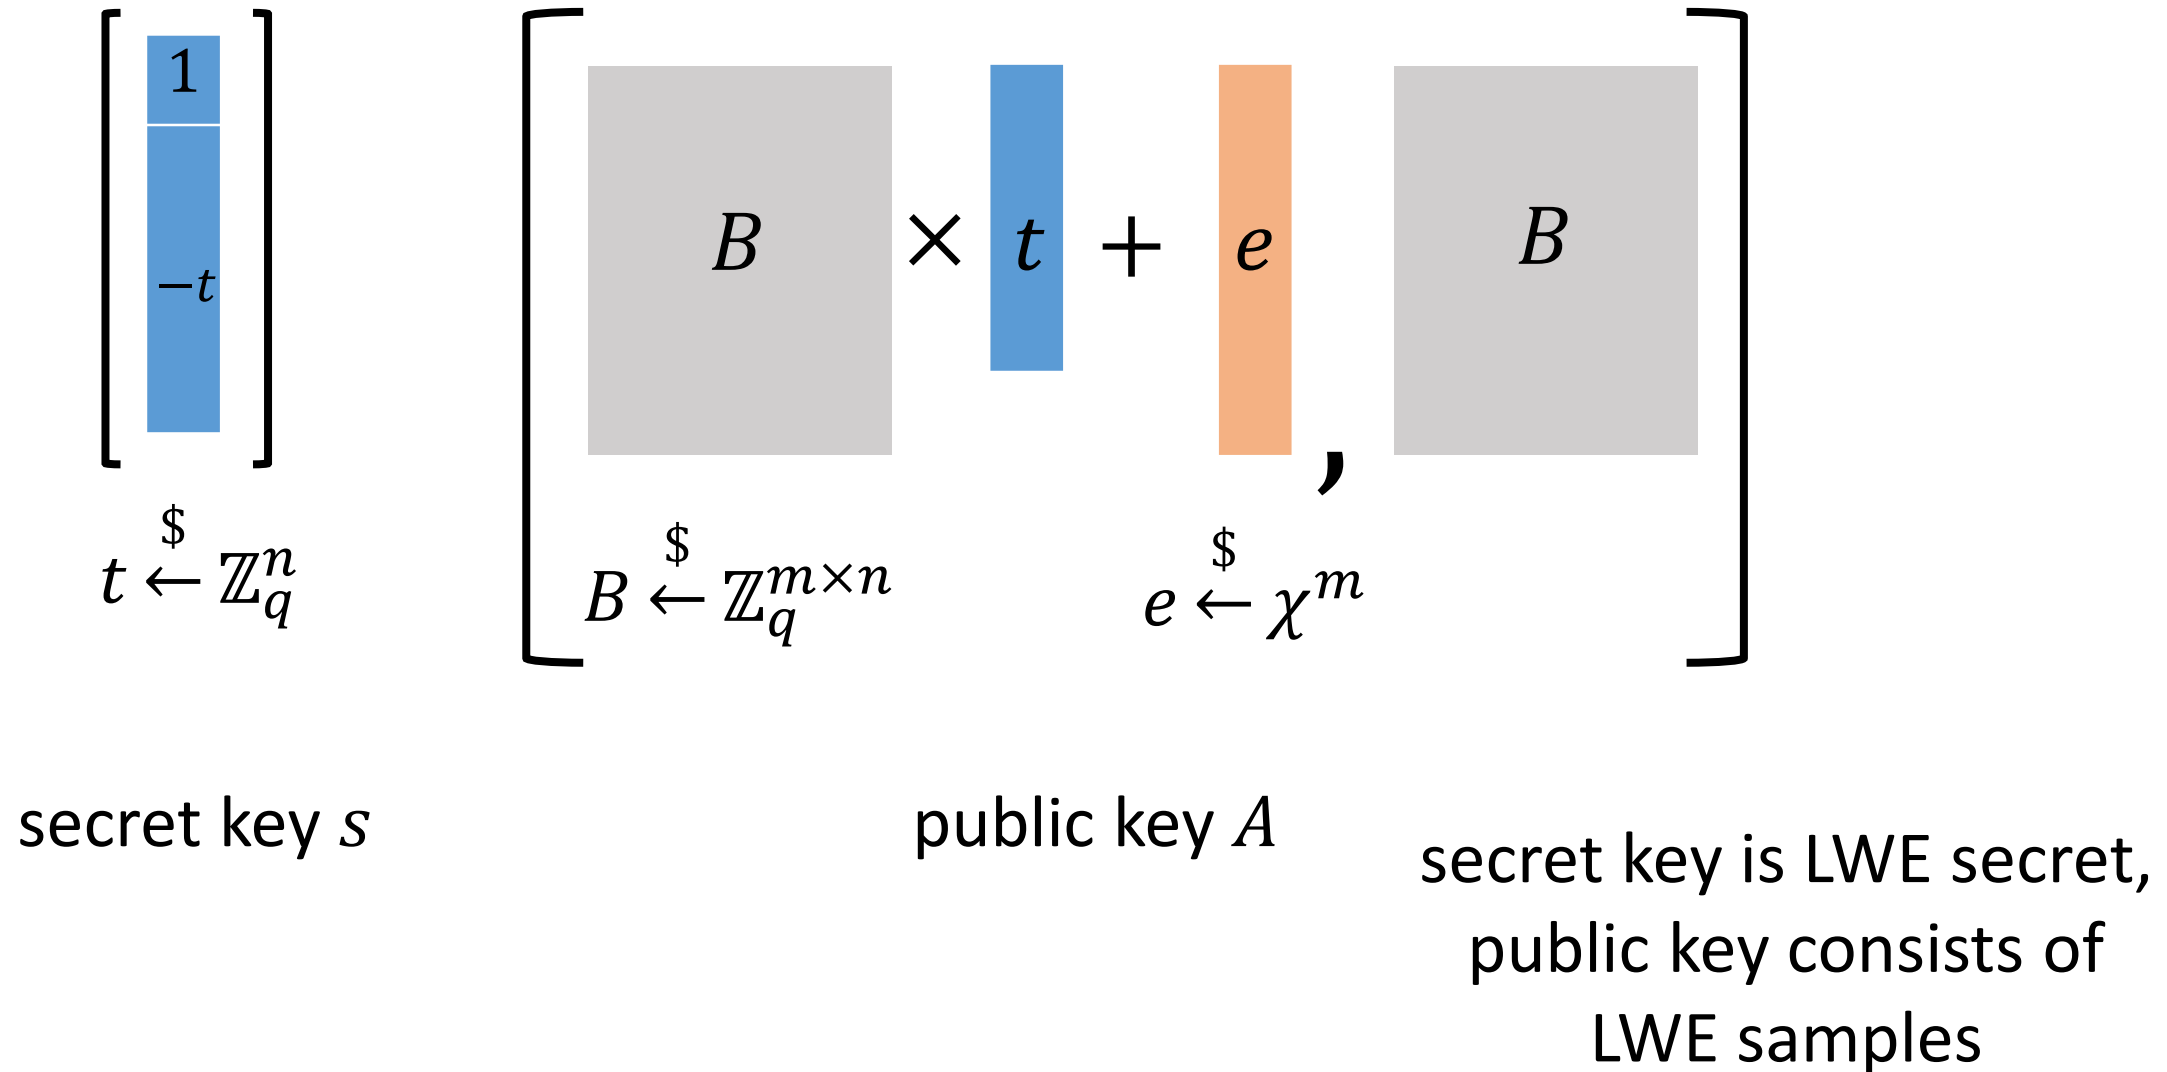

$$s \stackrel{\$}{\leftarrow} \mathbb{Z}_q^n \quad e \stackrel{\$}{\leftarrow} \chi^m$$

Learning with Errors (LWE)

A gold mine of applications!

- PKC: [Reg05], [KTX07], [Pei09]
- FHE: [BV11], [BGV12], [Bra12], [GSW13]
- IBE: [GPV08], [CHKP10], [ABB10]
- ABE: [GVW13], [BCG+14]
- FE: [AFV11]
- ... and many more!

Public Key Encryption from LWE [Reg05]

Regev Encryption

$$\left[\begin{array}{c} r^T \end{array} \right] \times \left[\begin{array}{c} Bt + e \\ B \end{array} \right] + \left[\begin{array}{c} m \cdot \lfloor \frac{q}{2} \rfloor \\ 0^n \end{array} \right]$$

$r \stackrel{\$}{\leftarrow} \{0,1\}^m$ public key $m \in \{0,1\}$

random subset sum of rows in public key, with message embedded in leading component

Regev Decryption

$$\begin{bmatrix} r^T(Bt + e) + m \cdot \lfloor \frac{q}{2} \rfloor \\ r^T B \end{bmatrix} \times \begin{bmatrix} 1 \\ -t \end{bmatrix} = r^T B t + r^T e + m \cdot \lfloor \frac{q}{2} \rfloor - r^T B t$$

ciphertext secret key

multiplying by $\frac{2}{q}$ recovers the message if $r^T e$ is small

PKC from LWE: Regev Encryption [Reg05]

- **Private key:** choose $t \stackrel{\$}{\leftarrow} \mathbb{Z}_q^n$ and set $s \leftarrow (1, -t)$
- **Public key:** Choose $B \stackrel{\$}{\leftarrow} \mathbb{Z}_q^{m \times n}$, $e \stackrel{\$}{\leftarrow} \chi^m$ and compute
$$A \leftarrow (Bs + e, B) \in \mathbb{Z}_q^{m \times (n+1)}$$
- **Encrypt:** Choose random 0/1 vector $r \stackrel{\$}{\leftarrow} \{0,1\}^m$ and compute

$$r^T A + \left(m \cdot \left\lfloor \frac{q}{2} \right\rfloor, 0^n \right) \in \mathbb{Z}_q^{n+1}$$

- **Decrypt:** To decrypt ciphertext c , compute $\left\lfloor \frac{2}{q} \langle c, s \rangle \right\rfloor$

PKC from LWE: Regev Encryption [Reg05]

Correctness: if error sufficiently small ($< \frac{q}{4}$), then rounding yields the underlying message.

Security: random subset sum of (a_i, b_i) is statistically close to uniform (argument based on leftover hash lemma). Security follows by LWE assumption.

PKC from LWE: Regev Encryption [Reg05]

Key intuition: hide message by adding some noise;
everything works if noise is sufficiently small

Basic observation underlying many FHE
constructions

SWHE Construction from LWE

From SWHE to FHE

- Somewhat homomorphic encryption: encryption scheme that supports a *limited* number of operations
- All known constructions based on lattices:
 - Hide messages by adding noise
 - Homomorphic operations increase noise
- Gentry's blueprint [Gen09]: bootstrapping SWHE to FHE
 - Homomorphically evaluate the decryption circuit
 - Provides a way to “refresh” a ciphertext

A Simple SWHE Scheme [GSW13]

- Ciphertext are matrices
- Secret key is a vector $v \in \mathbb{Z}_q^n$
- A ciphertext C encrypts a message m if the following holds:

$$Cv = mv + e$$

where e is a small error term

- **Intuition:** the message is an *approximate* eigenvalue of the ciphertext

The GSW Scheme

- A ciphertext C encrypts a message m if the following holds:

$$Cv = mv + e$$

where e is a small error term

- Can decrypt if v has a “big” coefficient v_i by rounding:

$$\left\lfloor \frac{\langle C_i, v \rangle}{v_i} \right\rfloor = \left\lfloor \frac{mv_i + e}{v_i} \right\rfloor$$

where C_i denotes the i^{th} row of C

The GSW Scheme

- Homomorphic operations very natural – suppose C_1 encrypts m_1 and C_2 encrypts m_2

- Homomorphic addition: $C_1 + C_2$ (almost) encrypts $m_1 + m_2$:

$$(C_1 + C_2)v = (m_1 + m_2)v + \boxed{e_1 + e_2}$$

- Homomorphic multiplication: $C_1 C_2$ (almost) encrypts $m_1 m_2$:

$$C_1 C_2 v = (m_1 m_2)v + \boxed{m_2 e_1 + C_1 e_2}$$

- Everything works if **noise** is small enough

Constraining Noise Growth

- Recall Regev decryption:

$$m \leftarrow \left\lfloor \frac{2}{q} \langle c, s \rangle \right\rfloor$$

- Key operation is inner product
- Want transformation that preserves inner product while reducing “size” (norm) of vectors

Bit Decomposition

- Let $\ell = \lfloor \log_2 q \rfloor + 1$ and suppose $z \in \mathbb{Z}_q^n$
- $\text{BitDecomp}(z) = (z_{1,0}, \dots, z_{1,\ell-1}, \dots, z_{n,0}, \dots, z_{n,\ell-1})$ where $z_{i,j}$ is the j^{th} bit of the binary decomposition of z_i
- $\text{BitDecomp}^{-1}(z') = \left(\sum_{j=1}^{\ell} 2^j z'_{1,j}, \dots, \sum_{j=1}^{\ell} 2^j z'_{n,j} \right)$
- $\text{PowersOfTwo}(z) = (z_1, 2z_1, \dots, 2^{\ell-1} z_1, \dots, z_n, 2z_n, \dots, 2^{\ell-1} z_n)$

Bit Decomposition

- $\text{BitDecomp}(z) = (z_{1,0}, \dots, z_{1,\ell-1}, \dots, z_{n,0}, \dots, z_{n,\ell-1})$
- $\text{PowersOfTwo}(z) = (z_1, 2z_1, \dots, 2^{\ell-1}z_1, \dots, z_n, 2z_n, \dots, 2^{\ell-1}z_n)$

$$\langle \text{BitDecomp}(x), \text{PowersOfTwo}(y) \rangle = \langle x, y \rangle$$

Flattening a Vector

- $\text{Flatten}(z) = \text{BitDecomp}(\text{BitDecomp}^{-1}(z))$
- $\text{Flatten}(z)$ is a 0/1 vector even though z need not be a 0/1 vector

$$\langle x, \text{PowersOfTwo}(y) \rangle = \sum_{i=1}^n \sum_{j=0}^{\ell-1} x_{i,j} \cdot 2^j y_i$$

Preserves inner
product with
 $\text{PowersOfTwo}(\cdot)$

$$\begin{aligned} &= \sum_{i=1}^n y_i \sum_{j=0}^{\ell-1} 2^j x_{i,j} \\ &= \langle \text{BitDecomp}^{-1}(x), y \rangle \\ &= \langle \text{Flatten}(x), \text{PowersOfTwo}(y) \rangle \end{aligned}$$

GSW Key Generation

PowersOfTwo

$$\begin{pmatrix} 1 \\ -t \end{pmatrix}$$

$t \stackrel{\$}{\leftarrow} \mathbb{Z}_q^n$

secret key
PowersOfTwo(s)

Regev-like, but where we apply PowersOfTwo to the secret

$$\left[\begin{array}{c} B \\ B \stackrel{\$}{\leftarrow} \mathbb{Z}_q^{m \times n} \end{array} \times \begin{array}{c} t \\ \text{blue bar} \end{array} + \begin{array}{c} e \\ \text{orange bar} \\ e \stackrel{\$}{\leftarrow} \chi^m \end{array}, \begin{array}{c} B \\ \text{grey bar} \end{array} \right]$$

public key A

Note: $As = Bt + e - Bt = e$

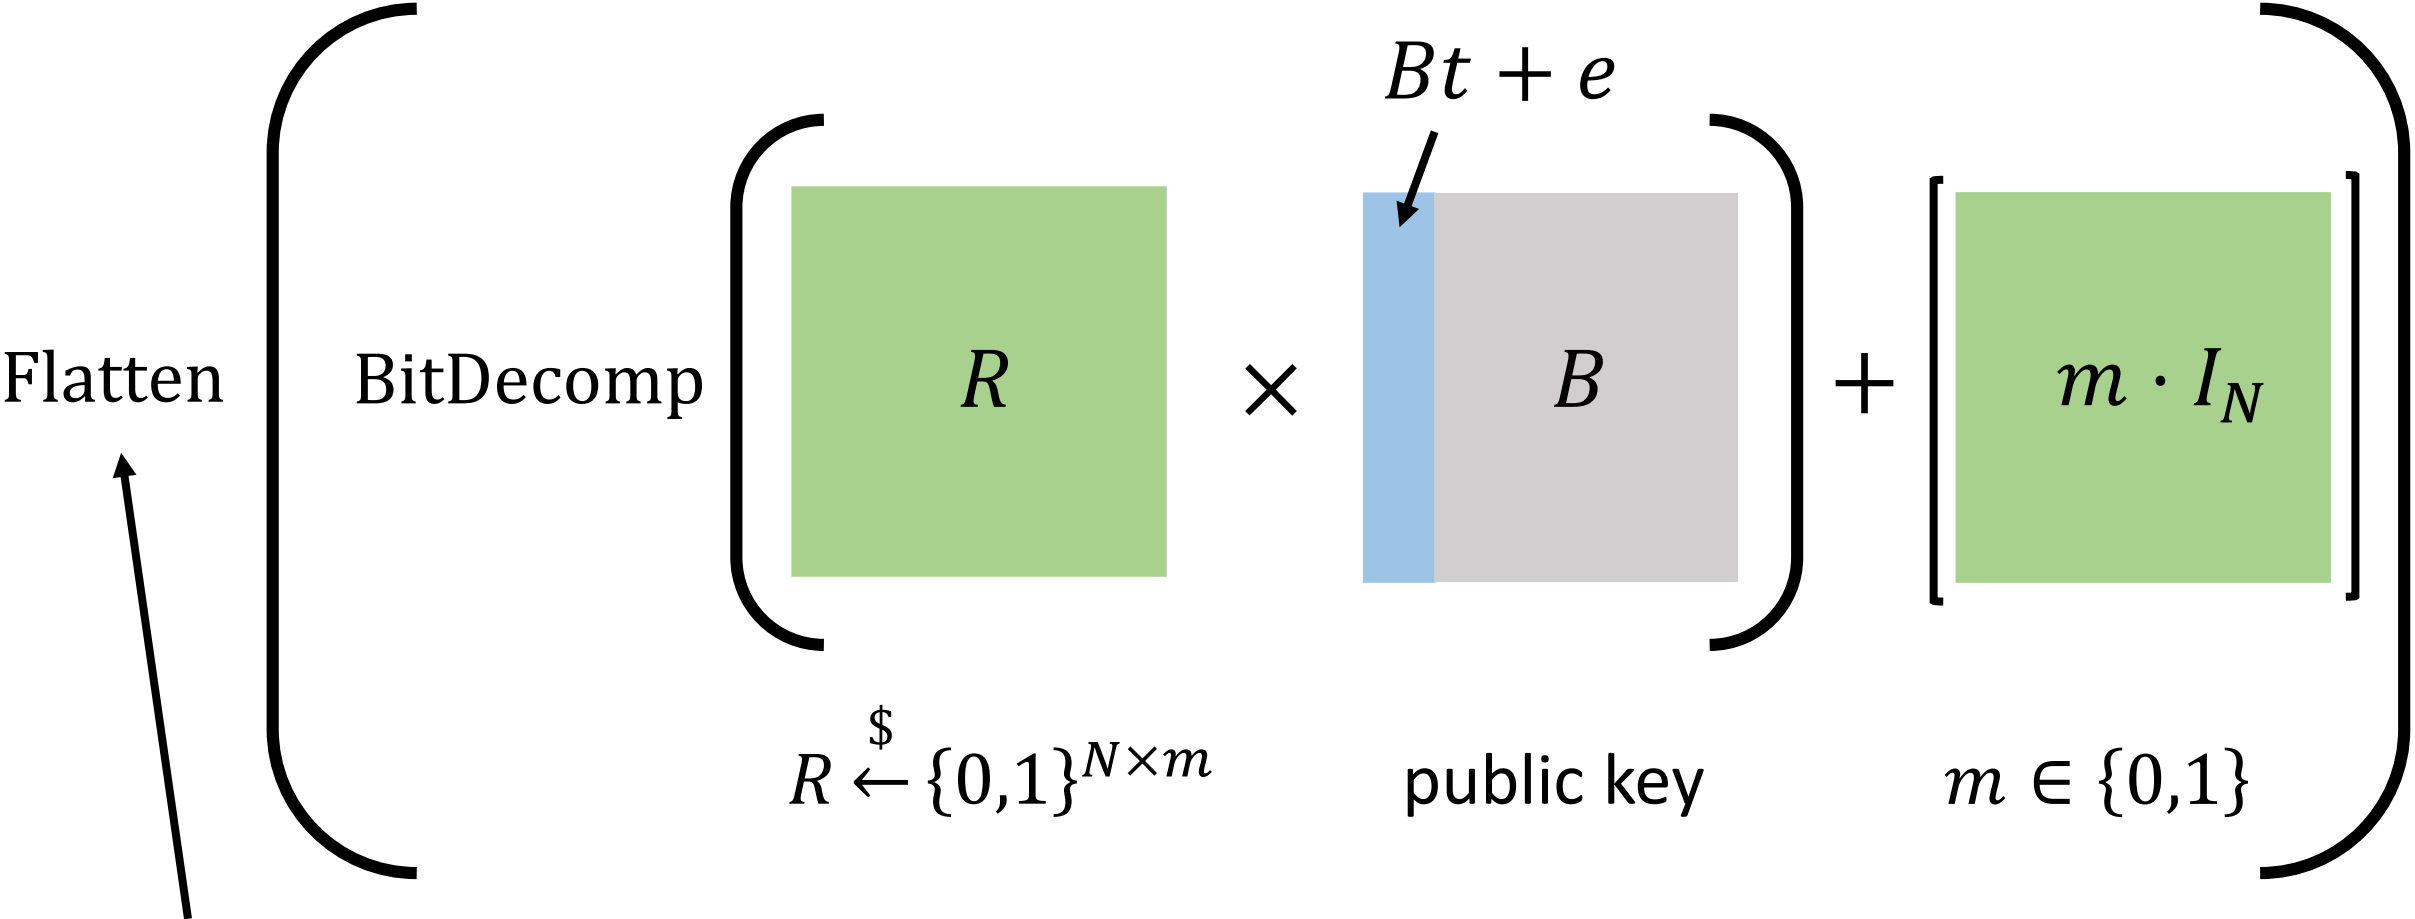

GSW Encryption

- Recall Regev decryption:

$$m \leftarrow \left\lfloor \frac{2}{q} \langle c, s \rangle \right\rfloor$$

- So far, replaced s with $\text{PowersOfTwo}(s)$, so to preserve inner product, we apply BitDecomp to the ciphertext c

GSW Encryption

Constrains norm of ciphertext, but preserves inner product $\langle c, \text{PowersOfTwo}(s) \rangle$

Approximate Eigenvalues

- Secret key is

$$v \leftarrow \text{PowersOfTwo}(s)$$

- Encryption of a message $m \in \{0,1\}$ given by

$$C \leftarrow \text{Flatten}(m \cdot I_N + \text{BitDecomp}(R \cdot A))$$

- Observe:

$$Cv = mv + RAs = mv + \boxed{Re}$$

Small since R is 0/1
matrix

Revisiting Homomorphic Operations

- Homomorphic operations very natural – suppose C_1 encrypts m_1 and C_2 encrypts m_2
- Homomorphic addition: $C_1 + C_2$ encrypts $m_1 + m_2$:
$$(C_1 + C_2)v = (m_1 + m_2)v + \boxed{e_1 + e_2}$$
- If e_1 and e_2 are small, then $e_1 + e_2$ is small

Revisiting Homomorphic Operations

- Homomorphic operations very natural – suppose C_1 encrypts m_1 and C_2 encrypts m_2

- Homomorphic multiplication: $C_1 C_2$ (almost) encrypts $m_1 m_2$:

$$C_1 C_2 v = (m_1 m_2) v + \boxed{m_2 e_1 + C_1 e_2}$$

- Noise increases based on
 - $|m_2|$: OK since $m_2 \in \{0,1\}$
 - $\|C_1\|$: OK since C_1 is 0/1 matrix

Revisiting Homomorphic Operations

- But homomorphic operations might produce matrix that is not 0/1
- Can use the Flatten operation again!
- Homomorphic addition: $\text{Flatten}(C_1 + C_2)$
- Homomorphic multiplication: $\text{Flatten}(C_1 C_2)$
- Ciphertext always consist of 0/1 matrices

Brief Note on Security [High-Level]

- Public key components are simply LWE samples
- Ciphertext components are very similar to Regev encryptions (omitting a few small details, but a very similar proof carries through), and hardness derives from LWE
