

# Computing on Encrypted Data

Secure Internet of Things Seminar

David Wu

January, 2015

# New Applications in the Internet of Things

*Pacific Gas and Electric Company*

aggregation + analytics

usage statistics and reports

report energy consumption

Smart Homes

# The Power of the Cloud

Question: provide  
service, preserve  
privacy

analytics  
recommendations  
personalization

lots of user  
information = big  
incentives

# Secure Multiparty Computation (MPC)

Multiple parties want to compute a joint function on *private* inputs

at end of computation,  
each party learns the  
average power  
consumption

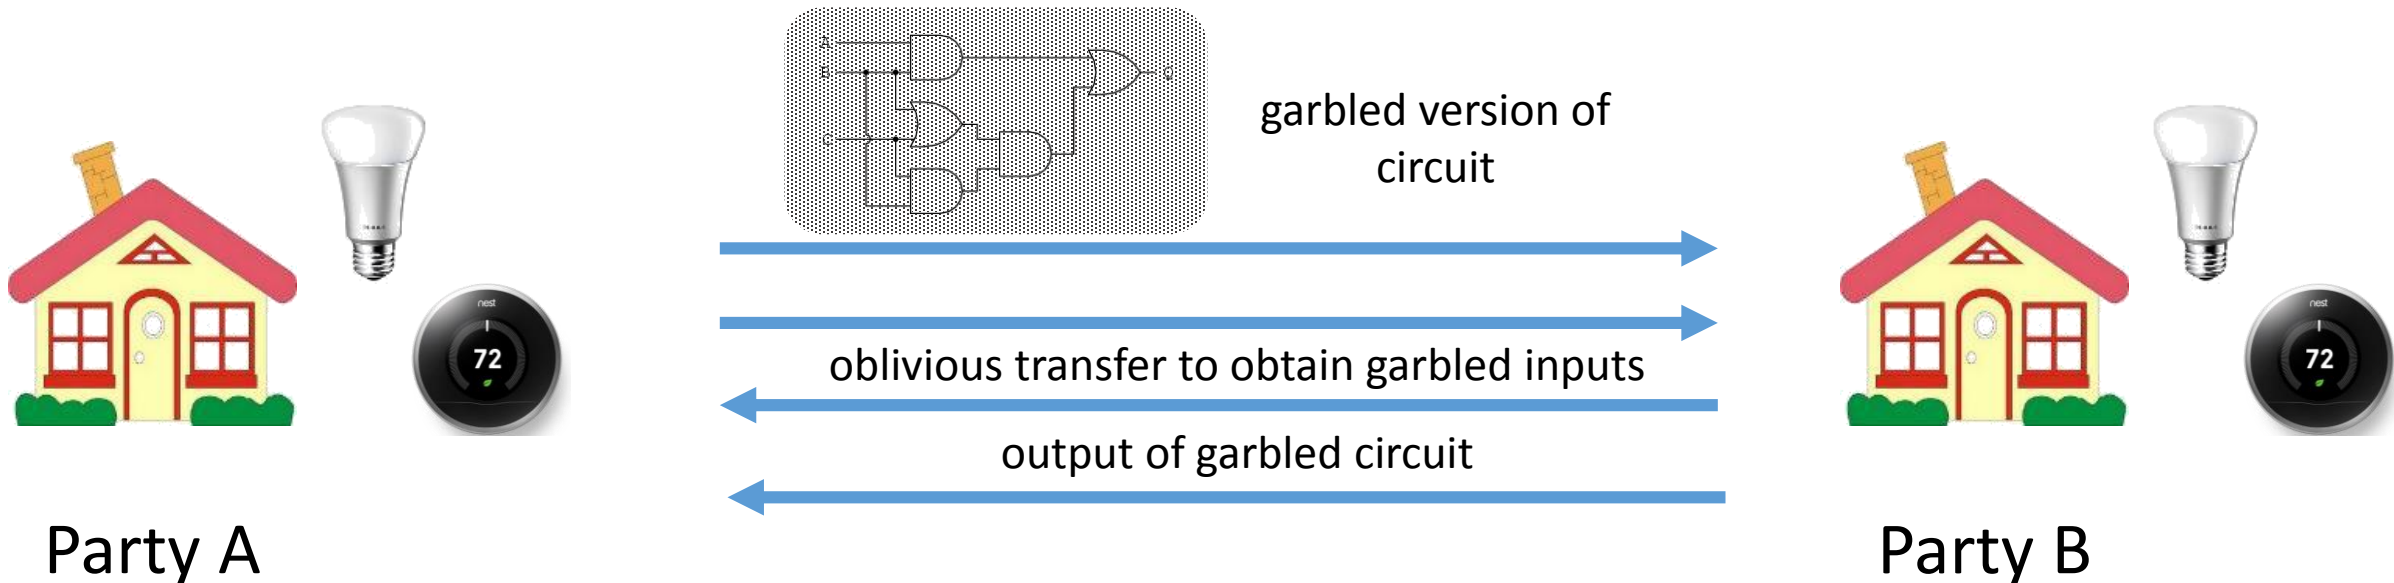

privacy guarantee: no party  
learns anything extra about  
other parties' inputs

private input: individual  
power consumption

# Two Party Computation (2PC)

- Simpler scenario: two-party computation (2PC)
- 2PC: Mostly “solved” problem: Yao’s circuits [Yao82]
  - Express function as a Boolean circuit

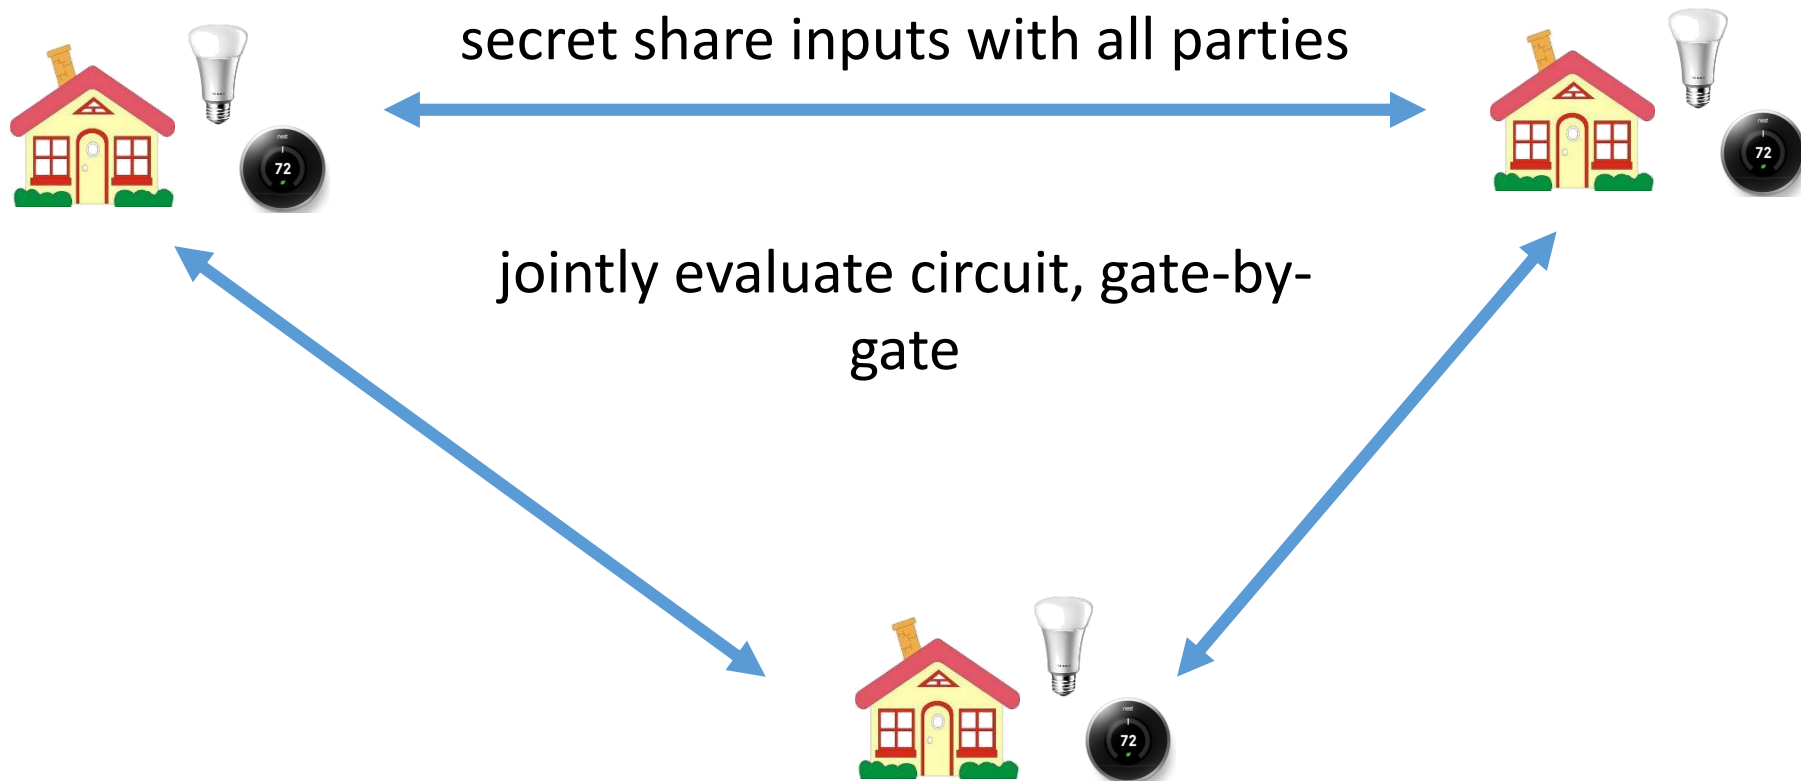

# Two-Party Computation (2PC)

- Yao's circuits very efficient and heavily optimized [KSS09]
  - Evaluating circuits with 1.29 **billion** gates in 18 minutes (1.2 gates /  $\mu$ s) [ALSZ13]
- Yao's circuit provides semi-honest security: malicious security via cut-and-choose, but not as efficient

# Going Beyond 2PC

- General MPC also “solved” [GMW87]

# Secure Multiparty Computation

- General MPC suffices to evaluate arbitrary functions amongst many parties: should be viewed as a feasibility result
- Limitations of general MPC
  - many rounds of communication / interaction
  - possibly large bandwidth
  - hard to coordinate interactions with large number of parties
- Other considerations (not discussed): fairness, guaranteeing output delivery

# This Talk: Homomorphic Encryption

Many rounds of interaction  
Boolean circuits (typically)

Few rounds of interaction  
Arithmetic circuits

GMW Protocol and  
General MPC

Custom Protocols

Homomorphic  
Encryption

General methods for secure computation

# Homomorphic Encryption

Homomorphic encryption scheme: encryption scheme that allows computation on ciphertexts

Comprises of three functions:

Must satisfy usual notion of semantic security

# Homomorphic Encryption

Homomorphic encryption scheme: encryption scheme that allows computation on ciphertexts

Comprises of three functions:

$$\text{Dec}_{sk} \left( \text{Eval}_f(ek, c_1, c_2) \right) = f(m_1, m_2)$$

# Fully Homomorphic Encryption (FHE)

Many homomorphic encryption schemes:

- ElGamal:  $f(m_0, m_1) = m_0 m_1$
- Paillier:  $f(m_0, m_1) = m_0 + m_1$

Fully homomorphic encryption: homomorphic with respect to **two** operations: addition and multiplication

- [BGN05]: one multiplication, many additions
- [Gen09]: first FHE construction from lattices

# Privately Outsourcing Computation

# Machine Learning in the Cloud

aggregation + analytics

3. Compute model homomorphically

1. Publish public key

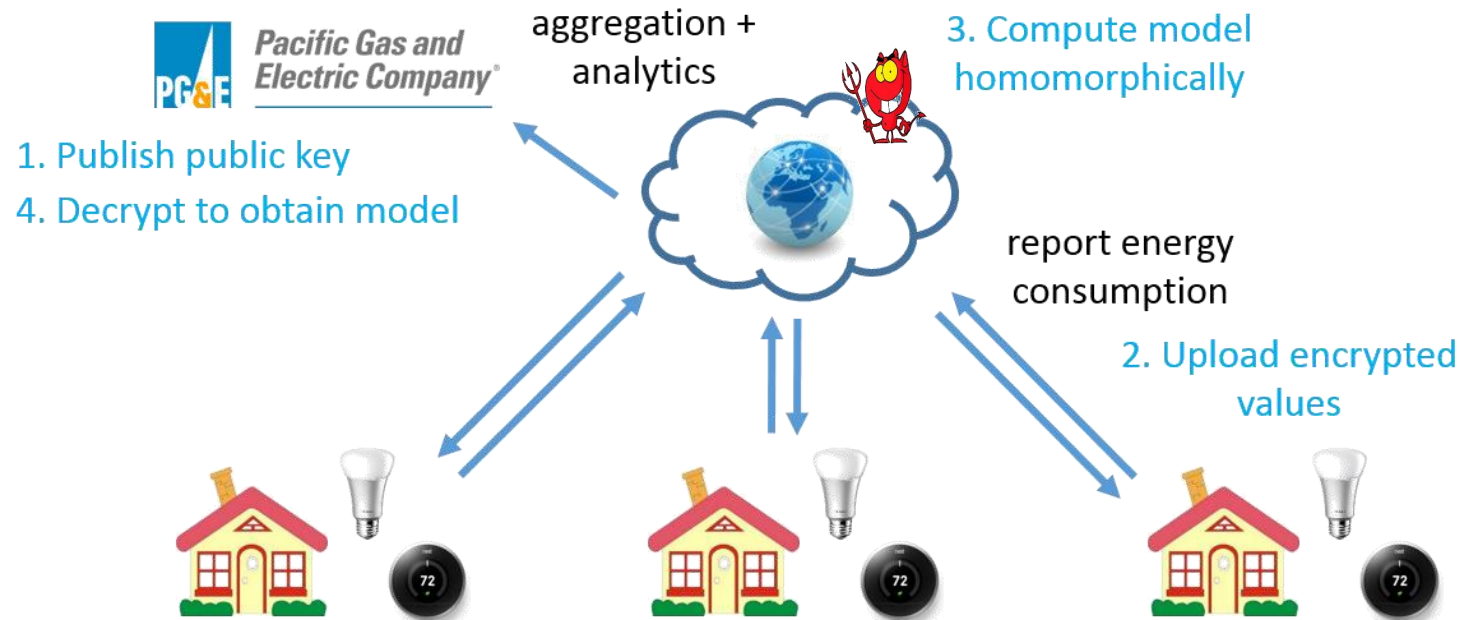

4. Decrypt to obtain model

report energy consumption

2. Upload encrypted values

# Machine Learning in the Cloud

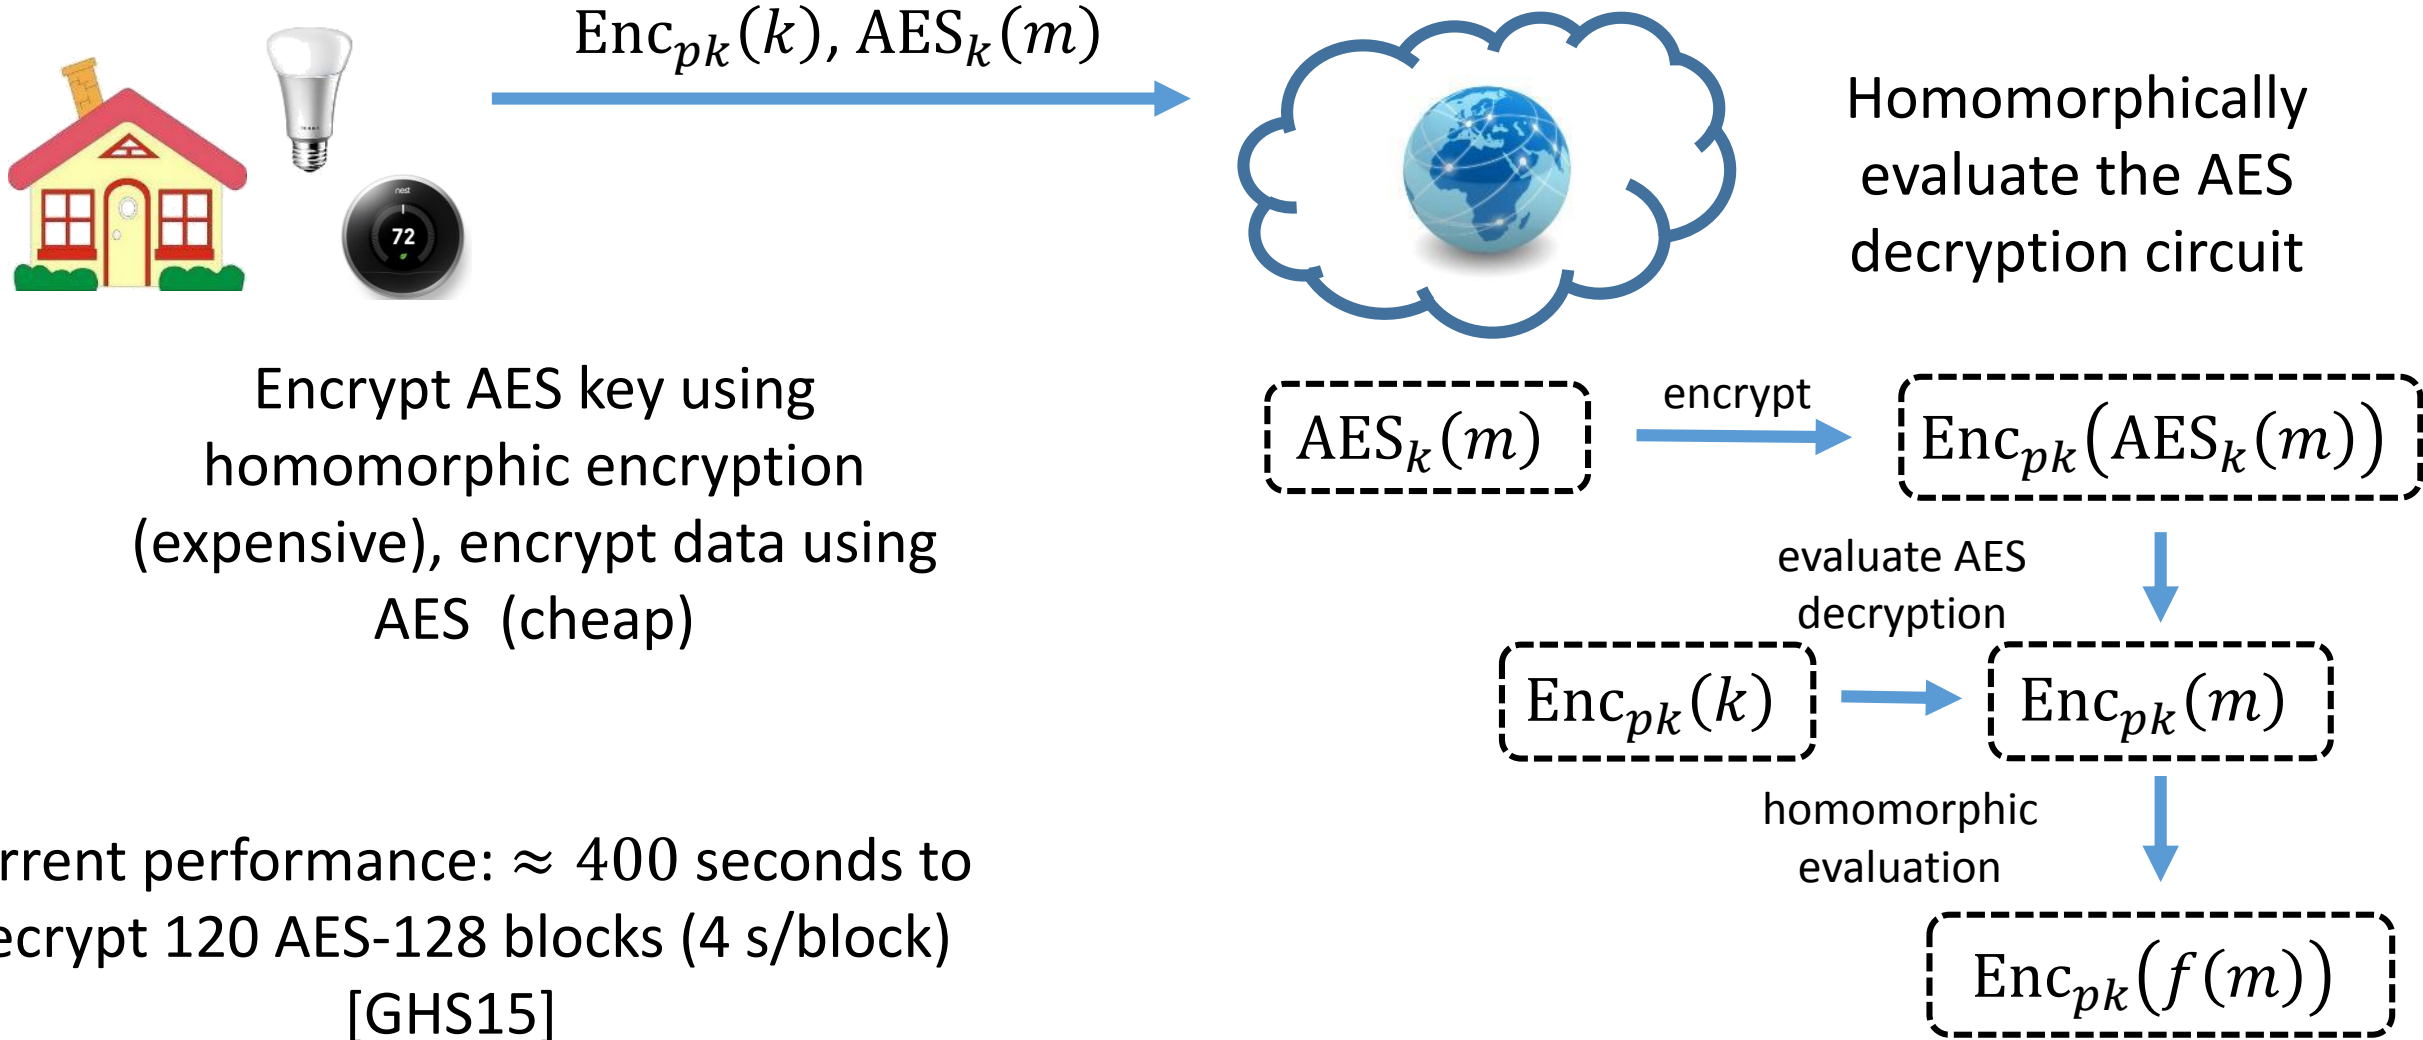

- Passive adversary sitting in the cloud does *not* see client data
- Power company only obtains resulting model, not individual data points (assuming no collusion)
- Parties only need to communicate with cloud (the power of public-key encryption)

# Big Data, Limited Computation

- Homomorphic encryption is expensive, especially compared to symmetric primitives such as AES
- Can be unsuitable for encrypting large volumes of data

# “Hybrid” Homomorphic Encryption

Current performance:  $\approx$  400 seconds to decrypt 120 AES-128 blocks (4 s/block) [GHS15]

# Constructing FHE

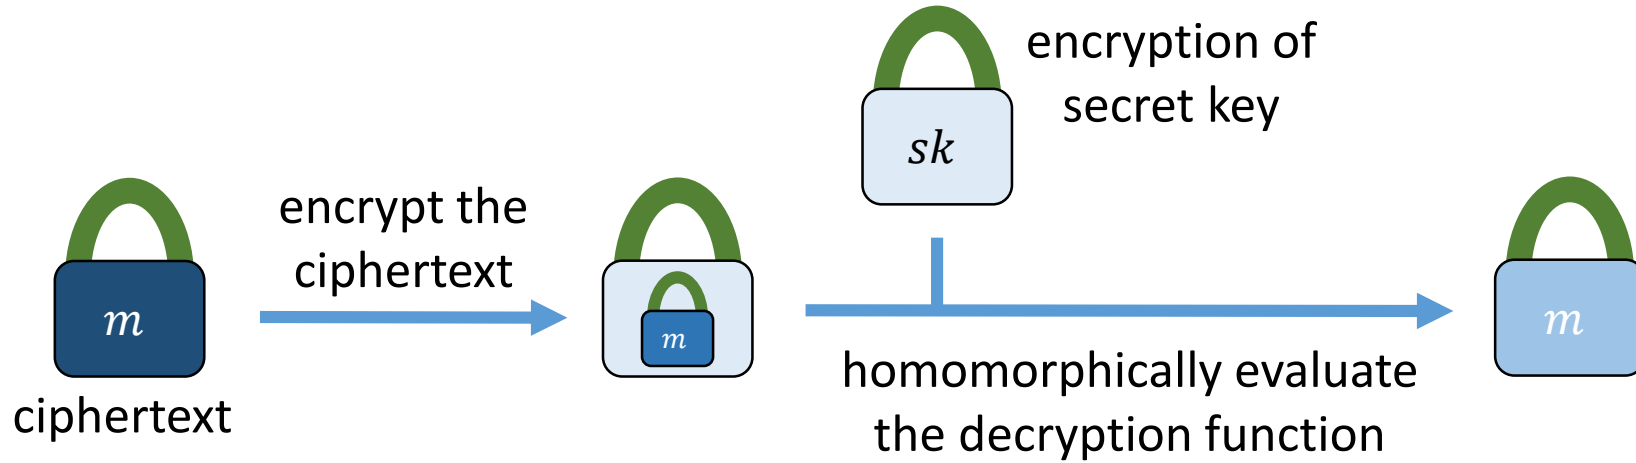

- FHE: can homomorphically compute arbitrary number of operations
- Difficult to construct – start with something simpler: *somewhat homomorphic encryption scheme (SWHE)*
- SWHE: can homomorphically evaluate a few operations (circuits of low depth)

# Gentry's Blueprint: SWHE to FHE

- Gentry described general *bootstrapping* method of achieving FHE from SWHE [Gen'09]
- Starting point: SWHE scheme that can evaluate its own decryption circuit

# Gentry's Blueprint: From SWHE to FHE

recrypt  
functionality

# Bootstrappable SWHE

- First bootstrappable construction by Gentry based on ideal lattices [Gen09]
- Tons of progress in constructions of FHE in the ensuing years [vDGHV10, SV10, BV11a, BV11b, Bra12, BGV12, GHS12, GSW13], and more!
- Have been simplified enough that the description can fit in a blog post [BB12]

# Conceptually Simple FHE [GSW13]

- Ciphertexts are  $n \times n$  matrices over  $\mathbb{Z}_q$
- Secret key is a vector  $v \in \mathbb{Z}_q^n$

$v$  is a “noisy” eigenvector of  $C$

The diagram shows the encryption relation:  $C \times v = m \times v + e$ . On the left, a green square labeled  $C$  is multiplied by a blue vertical rectangle labeled  $v$ . This is equal to an orange square labeled  $m$  multiplied by a blue vertical rectangle labeled  $v$ , plus a gray vertical rectangle labeled  $e$ . A blue arrow points from the text above to the  $v$  in the noise term.

ciphertext      secret key      message      noise

Encryption of  $m$  satisfies above relation

# Conceptually Simple FHE [GSW13]

- Suppose that  $v$  has a “large” component  $v_i$

$$\begin{array}{ccccccc} \boxed{C} & \times & \boxed{v} & = & \boxed{m} & \times & \boxed{v} & + & \boxed{e} \\ \text{ciphertext} & & \text{secret key} & & \text{message} & & & & \text{noise} \end{array}$$

- Can decrypt as follows:

$$C_i \text{ is } i^{\text{th}} \text{ row of } C \quad \left[ \frac{\langle C_i, v \rangle}{v_i} \right] = \left[ \frac{mv_i + e_i}{v_i} \right] = m \quad \text{Relation holds if } \left| \frac{e_i}{v_i} \right| < \frac{1}{2}$$

# Conceptually Simple FHE [GSW13]

## Homomorphic addition

$$C_1 \times v = m_1 \times v + e_1$$

$$C_2 \times v = m_2 \times v + e_2$$

$$(C_1 + C_2) \times v = (m_1 + m_2) \times v + e_1 + e_2$$

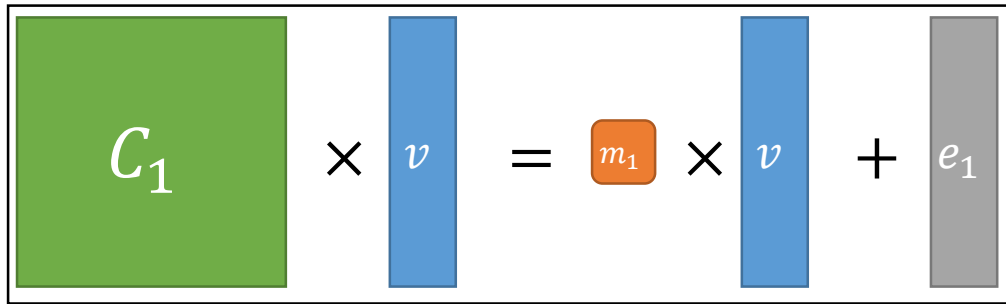

homomorphic addition is  
matrix addition

noise terms also add

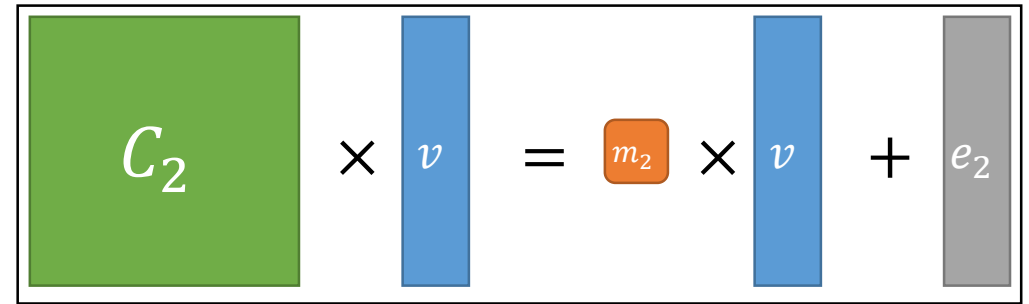

# Conceptually Simple FHE [GSW13]

## Homomorphic multiplication

A diagram illustrating the first step of homomorphic multiplication. It shows a green square labeled  $C_1$  multiplied by a blue vertical bar labeled  $v$ . This is equal to an orange square labeled  $m_1$  multiplied by the same blue vertical bar  $v$ , plus a gray vertical bar labeled  $e_1$ .

$$C_1 \times v = m_1 \times v + e_1$$

A diagram illustrating the second step of homomorphic multiplication. It shows a green square labeled  $C_2$  multiplied by a blue vertical bar labeled  $v$ . This is equal to an orange square labeled  $m_2$  multiplied by the same blue vertical bar  $v$ , plus a gray vertical bar labeled  $e_2$ .

$$C_2 \times v = m_2 \times v + e_2$$

$$(C_1 C_2)v = (m_1 m_2)v + C_1 e_2 + m_2 e_1$$

homomorphic multiplication  
is matrix multiplication

noise could blow up if  
 $C_1$  or  $m_2$  are not small

# Conceptually Simple FHE [GSW13]

- Basic principles: ciphertexts are matrices, messages are approximate eigenvalues
- Homomorphic operations correspond to matrix addition and multiplication (and some tricks to constrain noise)
- Hardness based on learning with errors (LWE) [Reg05]

# The Story so Far...

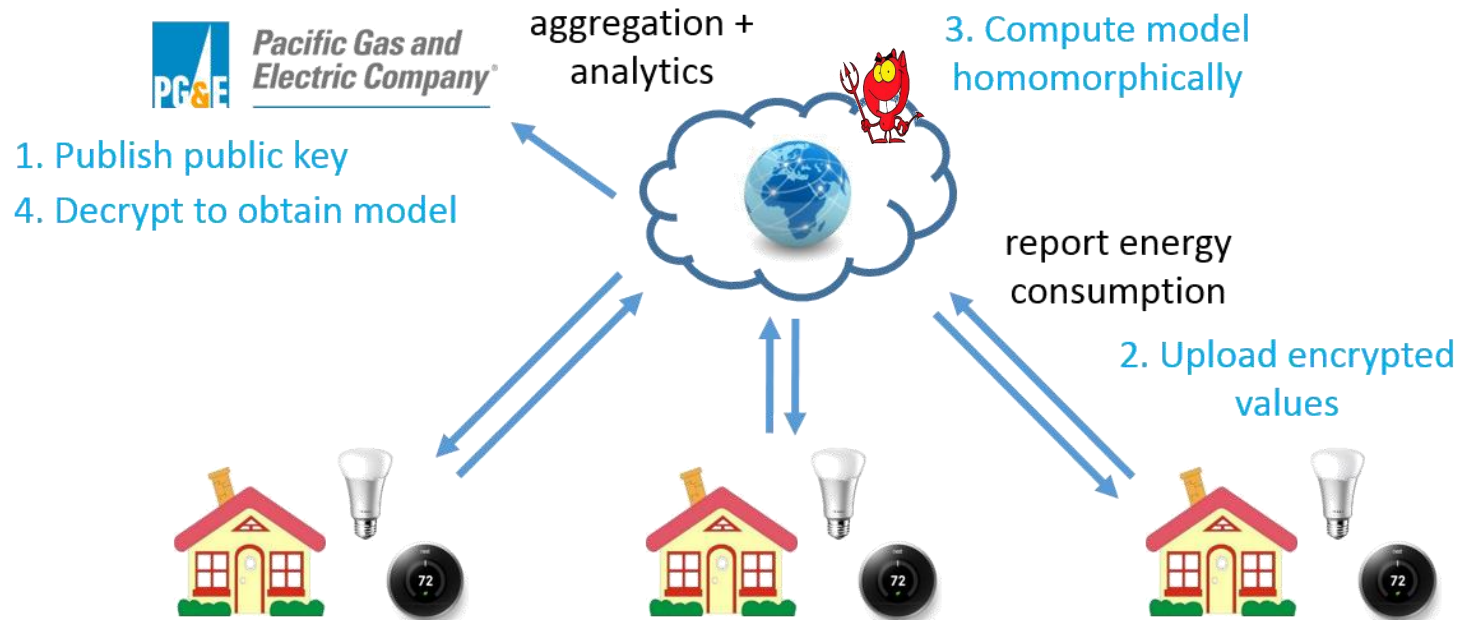

- Simple FHE schemes exist
- But... bootstrapping is expensive!
  - At 76 bits of security: each bootstrapping operation requires 320 seconds and 3.4 GB of memory [HS14]
  - Other implementations exist, but generally less flexible / efficient
- SWHE (without bootstrapping) closer to practical: can evaluate shallow circuits

# Application: Statistical Analysis

- Consider simple statistical models: computing the mean or covariance (for example, average power consumption)
- Problem: given  $n$  vectors  $x_1, \dots, x_n$ , compute
  - Mean:  $\mu = \frac{1}{n} \sum_{i=1}^n x_i$
  - Covariance:  $\Sigma_X = \frac{1}{n^2} (nX^T X -$

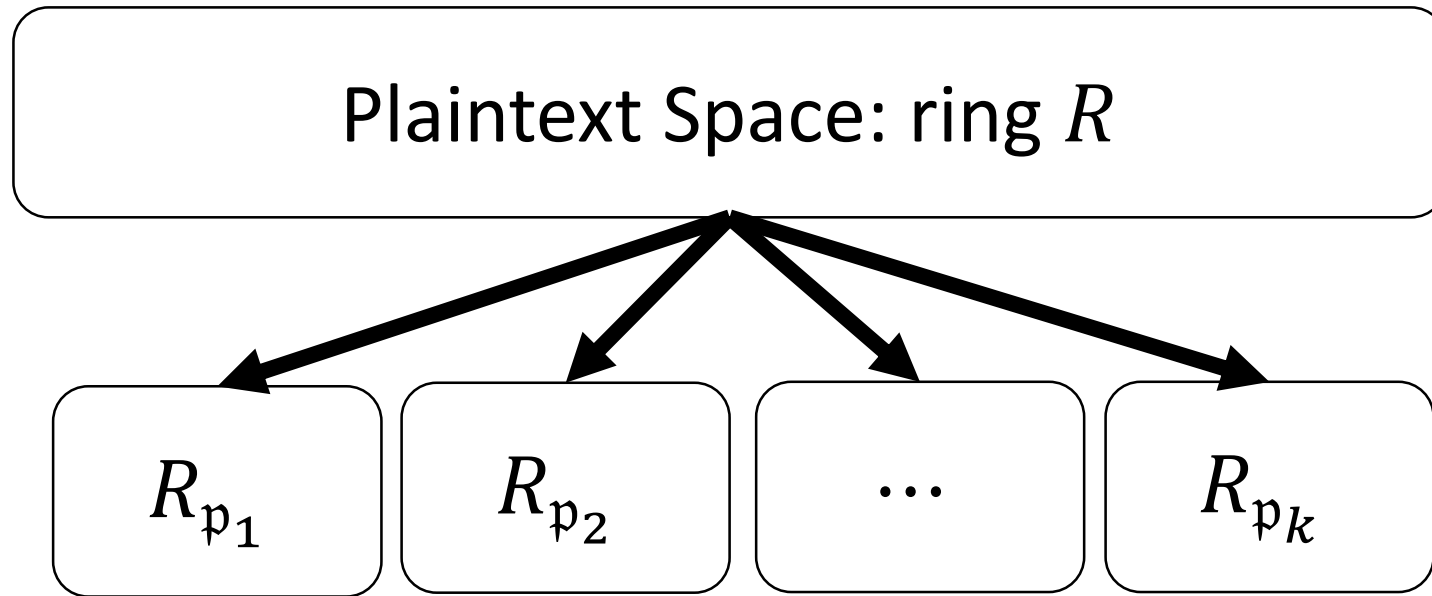

# Application: Statistical Analysis

- Can also perform linear regression: given design matrix  $X$  and response vector  $y$ , evaluate normal equations
$$\theta = (X^T X)^{-1} X^T y$$
- Matrix inversion (over  $\mathbb{Q}$ ) using Cramer's rule
- Depth  $n$  for  $n$ -dimensional data

# Batch Computation [SV11]

Algebraic structure of some schemes enable encryption + operations on vectors at no extra cost

Chinese Remainder Theorem:  $R \cong \bigotimes_{i=1}^k R_{p_i}$

# Batch Computation [SV11]

Encrypt + process array of values at no extra cost:

1	2	3	4
---	---	---	---

+

7	5	3	1
---	---	---	---

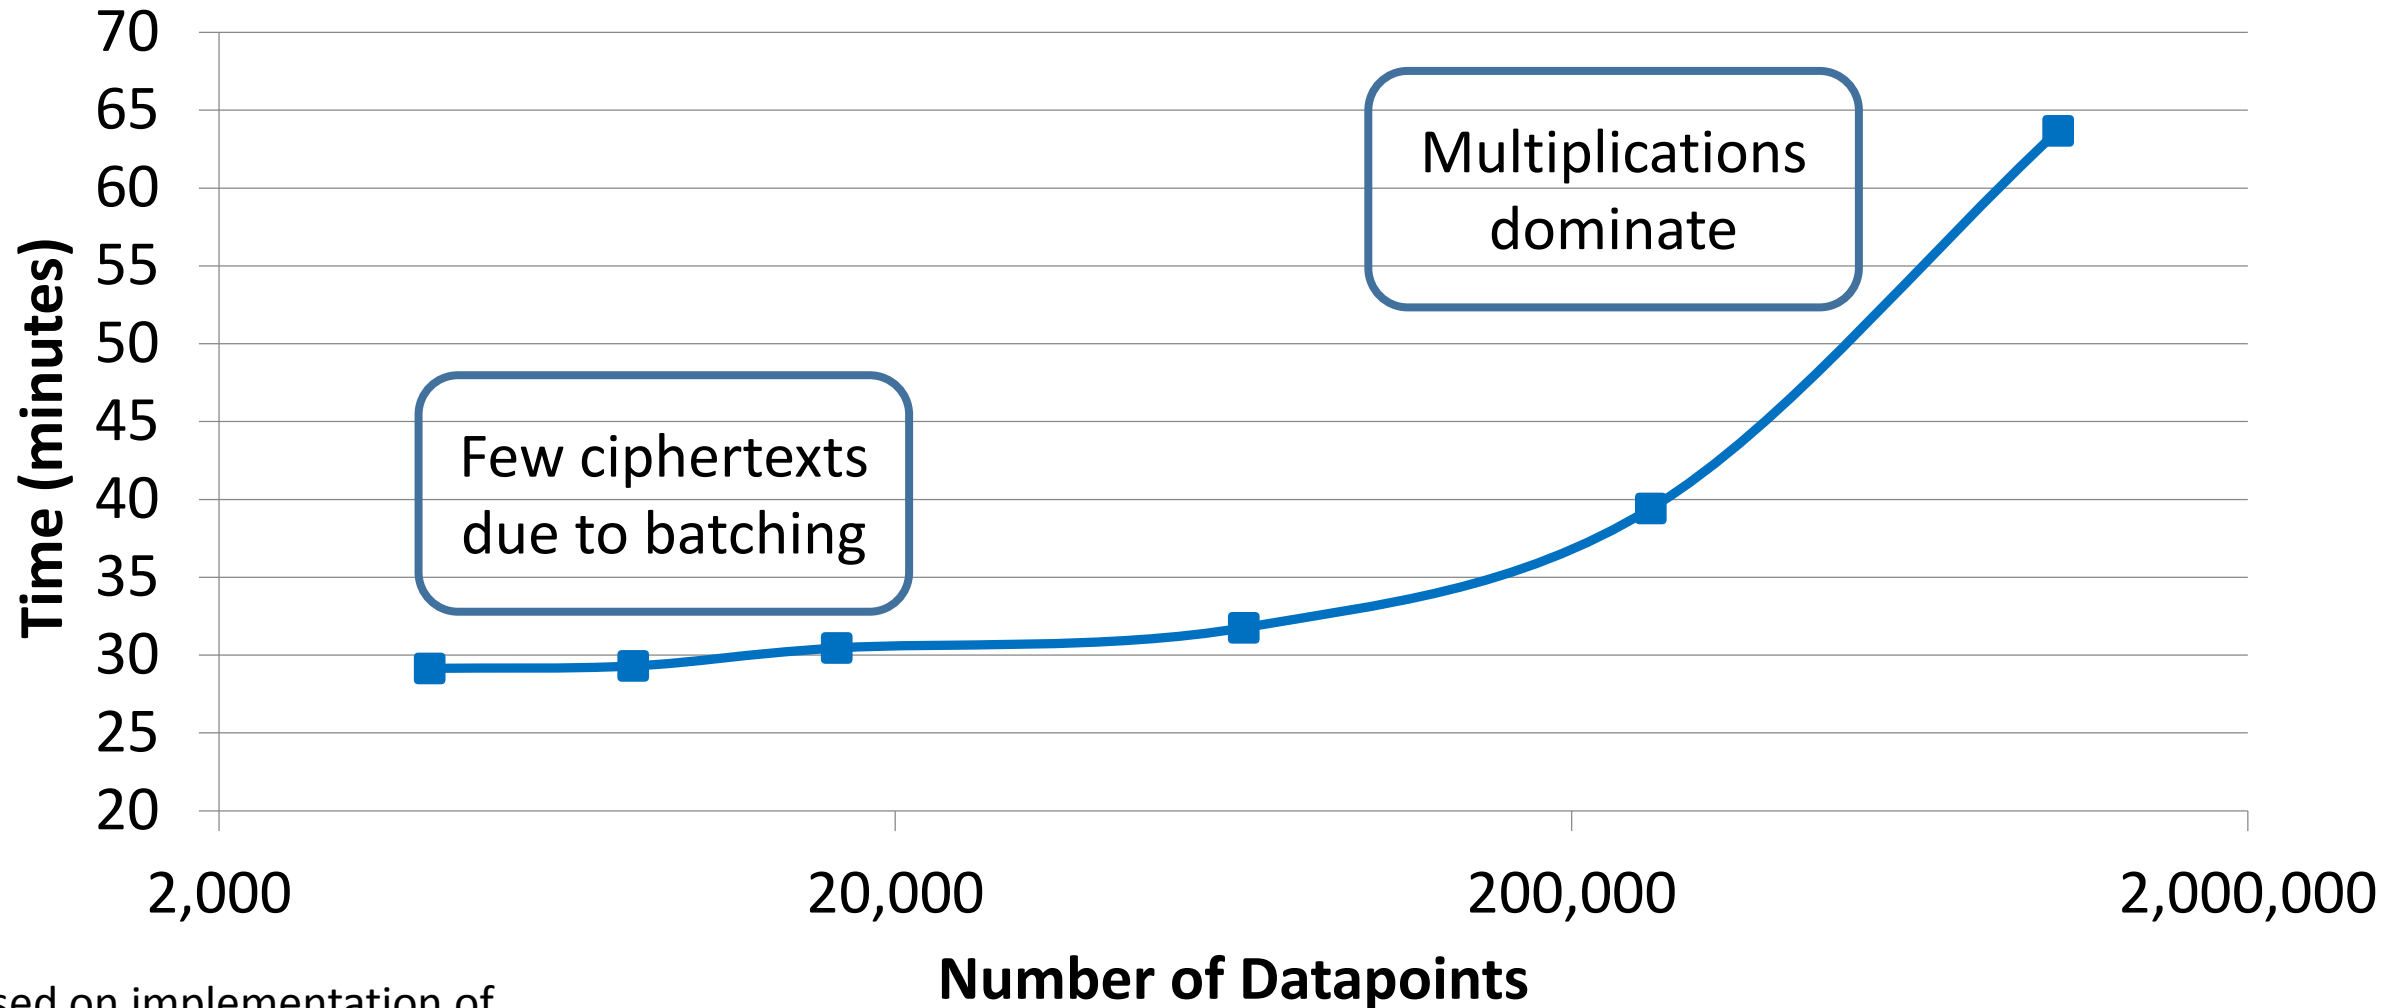

8	7	6	5
---	---	---	---

One homomorphic operation

In practice:  $\geq 5000$  slots

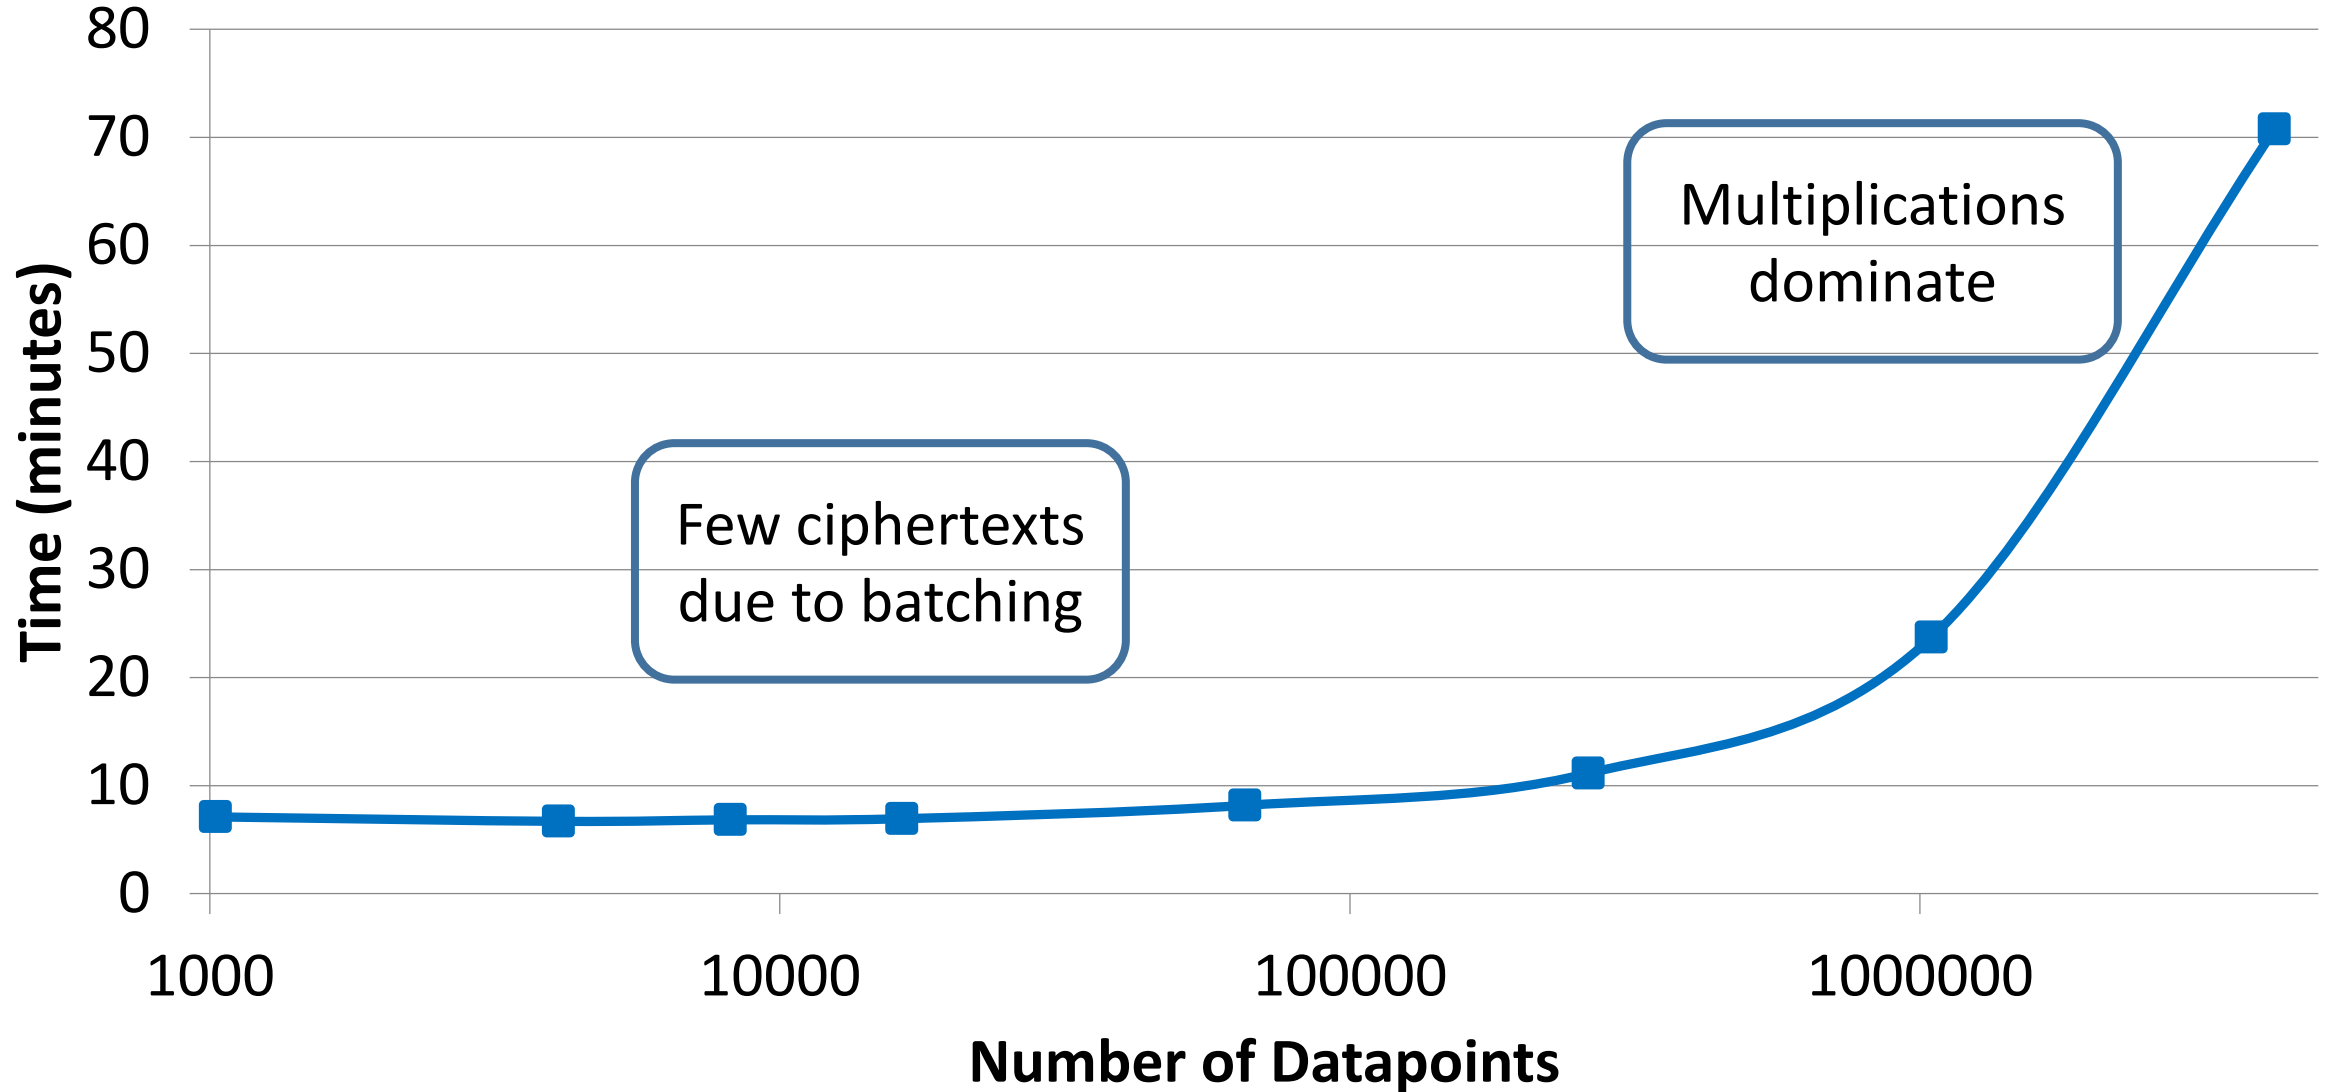

# Time to Compute Mean and Covariance over Encrypted Data (Dimension 4)

Based on implementation of Brakerski's scheme [Bra12]

# Time to Perform Linear Regression on Encrypted Data (2 Dimensions)

# Application: Private Information Retrieval

client learns record  $i$ , server learns nothing

# PIR from Homomorphic Encryption [KO97]

$$\begin{bmatrix} v_{11} & v_{12} & v_{13} \\ v_{21} & v_{22} & v_{23} \\ v_{31} & v_{32} & v_{33} \end{bmatrix}$$

represent database as  
matrix

×

$$\begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$$

query is an  
encrypted basis  
vector

=

$$\begin{bmatrix} v_{11} \\ v_{21} \\ v_{31} \end{bmatrix}$$

response

$O(\sqrt{n})$   
communication

server evaluates inner product

database components in the clear: additive homomorphism suffices

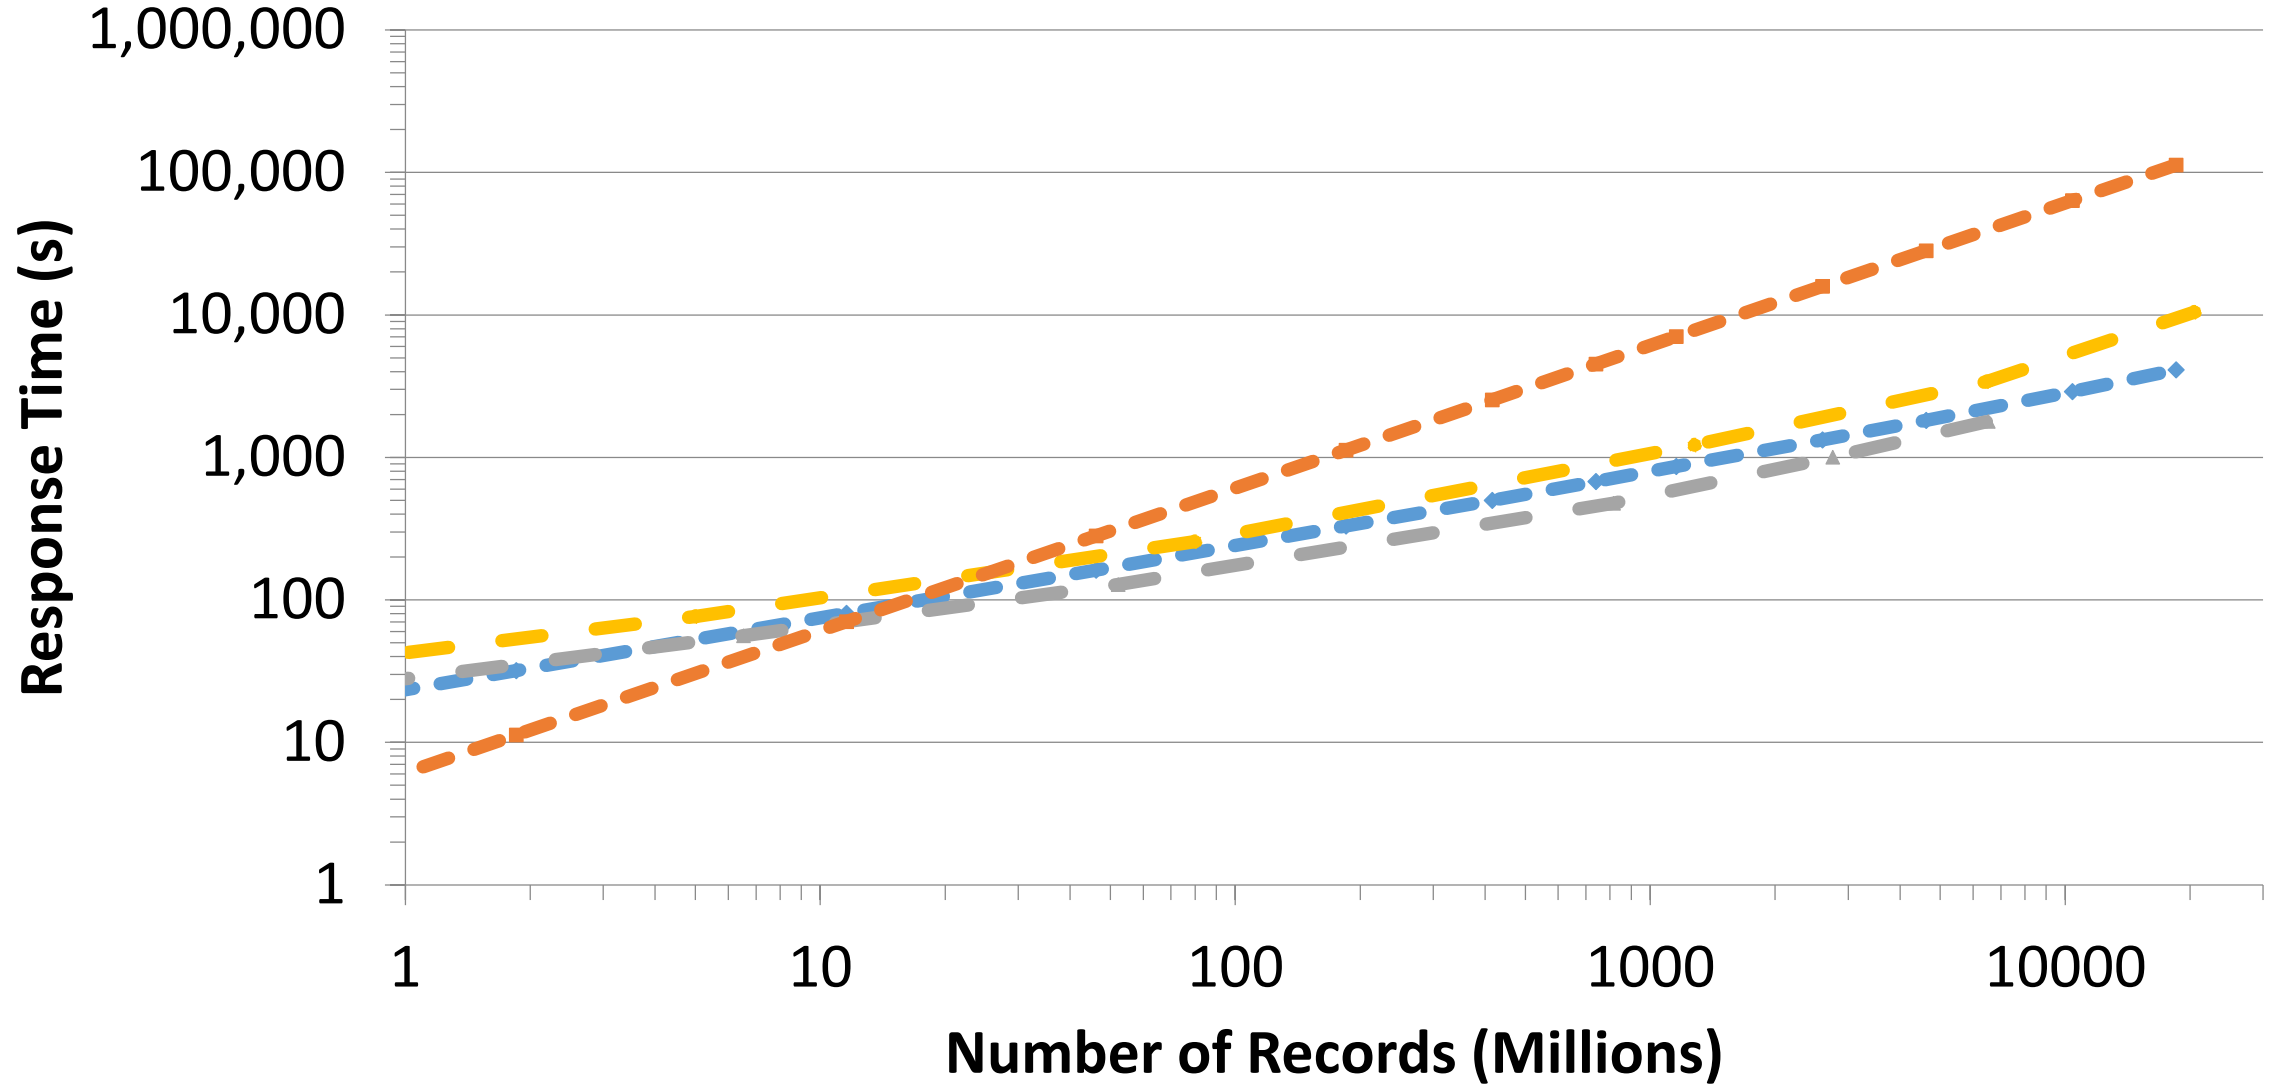

# PIR from Homomorphic Encryption

- $O(\sqrt{n})$  communication with additive homomorphism alone
- Naturally generalizes:
  - $O(\sqrt[3]{n})$  with one multiplication
  - $O(\sqrt[k]{n})$  with degree  $(k - 1)$ -homomorphism
- Benefits tremendously from batching

split database into  
many small  
databases, query in  
parallel

# FHE-PIR Timing Results (5 Mbps)

→ FHE-PIR (d = 2)    — FHE-PIR (d = 3)    — FHE-PIR (d = 4)    — Trivial PIR

# PIR from Homomorphic Encryption

- Outperforms trivial PIR for very large databases
- However, recursive KO-PIR with additive homomorphism is still state-of-the-art

# Concluding Remarks

- Internet of Things brings many security challenges
- Many generic cryptographic tools: 2PC, MPC, FHE
  - 2PC/MPC work well for small number of parties
  - SWHE/FHE preferable with many parties (IoT scale)
- FHE still nascent technology – should be viewed as a “proof-of-concept” rather than practical solution
- SWHE closer to practical, suitable for evaluating simple (low-depth) functionalities
- Big open problem to develop more practical constructions!
